The main difference between a CT Scan and an MRI is the way the two scanning devices work. The CT scan uses x-rays to scan the body and to capture pictures in the details. CT Scan exposes one to forms of radiation. The CT machines have become faster over time thus the patient is exposed to a lower level of radiation today.

Difference Between CT Scan and MRI of Brain - HRF
A Brief Overview of How CT and MRI Works. For both CT (left) and MRI (right) scans you will lie on a moving table and be put into a circular machine that looks like a big doughnut. The table will move your body into the doughnut hole. The scan will then be performed. You may or may not get IV contrast through an IV.

CT scans utilize X-rays to produce images of the inside of the body while MRI (magnetic resonance imaging) uses powerful magnetic fields and radio frequency pulses to produce detailed pictures of organs and other internal body structures. CT scans use radiation (X-rays), and MRIs do not. MRIs provide more detailed information about the inner organs (soft tissues) such as the brain, skeletal system, reproductive system and other organ systems than is provided by a CT scan.
